

# Non-uniform Randomized Sampling for Multivariate Approximation by High Order Parzen Windows<sup>†</sup>

Xiang-Jun Zhou, Lei Shi and Ding-Xuan Zhou

## Abstract

We consider approximation of multivariate functions in Sobolev spaces by high order Parzen windows in a non-uniform sampling setting. Sampling points are neither i.i.d. nor regular, but are noised from regular grids by non-uniform shifts of a probability density function. Sample function values at sampling points are drawn according to probability measures with expected values being values of the approximated function. The approximation orders are estimated by means of regularity of the approximated function, the density function and the order of the Parzen windows, under suitable choices of the scaling parameter.

**Short title:** Randomized Approximation by Parzen Windows

**Key words and phrases:** Multivariate approximation, Sobolev spaces, non-uniform randomized sampling, high order Parzen windows, convergence rates

**AMS Subject Classification Numbers:** 68T05, 62J02

## 1 Introduction and Formal Setting

We consider approximation of functions on  $\mathbb{R}^n$  from samples of type  $\mathbf{z} = \{(x_i, y_i)\}_{i \in \mathbb{Z}^n}$ . If  $f^*$  is a function to be approximated, then on our setting described below, the sample function value  $y_i$  at the sampling point  $x_i$  satisfies  $y_i \approx f^*(x_i)$ . In randomized sampling, the sampling points  $\{x_i\}$  are governed by some probability distributions.

In this paper we continue our study [11] on randomized sampling of functions on  $\mathbb{R}^n$  by means of high order Parzen windows

$$f_{\mathbf{z}, \sigma}(x) = \sum_{i \in \mathbb{Z}^n} y_i \Phi\left(\frac{x}{\sigma}, \frac{x_i}{\sigma}\right), \quad x \in \mathbb{R}^n. \quad (1.1)$$

---

<sup>†</sup> The work described in this paper is supported partially by the Research Grants Council of Hong Kong [Project No. CityU 103405], National Science Fund for Distinguished Young Scholars of China [Project No. 10529101], and National Basic Research Program of China [Project No. 973-2006CB303102].

Here  $\Phi : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$  is a window function,  $\sigma > 0$  is a window width. Under some conditions on the approximated function  $f^*$ , window function  $\Phi$  and noise controlling  $y_i - f^*(x_i)$ , the error in  $L^2(\mathbb{R}^n)$  between  $f^*$  and  $f_{\mathbf{z},\sigma}$  (with normalization) is analyzed in [11] when  $\{x_i\}_{i \in \mathbb{Z}^n}$  is drawn randomly from a sequence of probability densities  $\{p(\cdot - hi)\}_{i \in \mathbb{Z}^n}$  for some fixed density function  $p$  on  $\mathbb{R}^n$  and some grid size  $h > 0$ . In that setting,  $\{x_i\}$  is uniform in expectation:  $\mathbf{E}(x_i) = hi + \mathbf{E}(p)$  for each  $i \in \mathbb{Z}^n$ .

The purpose of this paper is to establish improvements of the above result in two directions. Firstly we consider a non-uniform setting in the sense that the sampling points  $\{x_i\}_{i \in \mathbb{Z}^n}$  are drawn according to the probability density functions  $\{p(\cdot - t_i)\}$  with non-uniform nodes  $\{t_i\}$  satisfying  $\sup_{i \in \mathbb{Z}^n} |t_i - hi| \leq \Delta$ . The quantity  $\Delta > 0$  measures the degree of non-uniformity as in the literature of non-uniform sampling [1]. Secondly, we estimate bounds the error in Sobolev spaces  $H^s(\mathbb{R}^n)$  by allowing  $s \geq 0$ , not only in the space  $L^2(\mathbb{R}^n)$  with  $s = 0$ . To this end, the basic window function  $\Phi$  is defined in terms of the index  $s$ . Throughout the paper,  $0 \leq s < J$  are two integers. For  $\alpha = (\alpha_1, \dots, \alpha_n) \in \mathbb{Z}_+^n$  and  $x = (x^1, \dots, x^n) \in \mathbb{R}^n$ , we denote  $x^\alpha = \prod_{j=1}^n (x^j)^{\alpha_j}$ ,  $|\alpha| = \alpha_1 + \dots + \alpha_n$  and  $D^\alpha \Phi(x, u) = \frac{\partial^\alpha}{\partial x^\alpha} (\Phi(\cdot, u))(x)$ .

**Definition 1.** A function  $\Phi : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$  is called a **basic window function** of type  $(J, s)$  if it satisfies

- (i)  $\int_{\mathbb{R}^n} \Phi(x, u) du \equiv 1$  and  $\int_{\mathbb{R}^n} \Phi(x, u)(u - x)^\alpha du \equiv 0$  for  $0 < |\alpha| < J$ ,
- (ii) for some  $q > n + J$  and  $c_q > 0$ ,

$$|D^\alpha \Phi(x, u)| \leq \frac{c_q}{(1 + |x - u|)^q} \quad \forall x, u \in \mathbb{R}^n, 0 \leq |\alpha| \leq s. \quad (1.2)$$

Condition (i) above is called vanishing moment condition in the literature of multivariate approximation [3] or wavelets [4].

As in the literature of Shannon sampling [8] or online learning [9], we shall assume throughout the paper that the sample  $\mathbf{z} = \{(x_i, y_i)\}_{i \in \mathbb{Z}^n}$  is drawn independently from a sampling sequence  $\{\rho^{(i)}\}_{i \in \mathbb{Z}^n}$  of probability measures on  $Z := \mathbb{R}^n \times \mathbb{R}$  associated with  $(M, h, \Delta, p)$ .

**Definition 2.** Let  $M, \Delta > 0$ ,  $0 < h \leq 1$  and  $p$  be a probability density function on  $\mathbb{R}^n$ . Each  $x \in \mathbb{R}^n$  is assigned a Borel probability measure  $\rho_x$  supported on  $[-M, M]$ , and  $\{t_i\}_{i \in \mathbb{Z}^n} \subset \mathbb{R}^n$  is a sequence satisfying  $|t_i - hi| \leq \Delta$  for each  $i \in \mathbb{Z}^n$ . We call  $\{\rho^{(i)}\}_{i \in \mathbb{Z}^n}$  a **sampling sequence** associated with  $(M, h, \Delta, p)$  if for each  $i$ , the marginal distribution  $\rho_X^{(i)}$  of  $\rho^{(i)}$  on  $\mathbb{R}^n$  has density  $p(\cdot - t_i)$  and the conditional distribution of  $\rho^{(i)}$  at each  $x \in \mathbb{R}^n$  equals  $\rho_x$ .

Define a function  $f^*$  to be approximated by

$$f^*(x) = \int_{\mathbb{R}} y d\rho_x, \quad x \in \mathbb{R}^n. \quad (1.3)$$

## 2 Main Result

Our main result provides bounds for the approximation of the function  $f^*$  on  $\mathbb{R}^n$  by (normalized)  $f_{\mathbf{z},\sigma}$  in the Sobolev space  $H^s(\mathbb{R}^n)$  with norm  $\|f\|_{H^s(\mathbb{R}^n)} = \sum_{|\alpha| \leq s} \|D^\alpha f\|_{L^2(\mathbb{R}^n)}$ . Denote the variance of  $\rho_x$  by  $\sigma_x^2$ .

**Theorem 1.** *Let  $\Phi$  be a basic window function of type  $(J, s)$ . Assume  $f^* \in C^{J+s}(\mathbb{R}^n)$ ,  $p \in C^{J+s}(\mathbb{R}^n)$  and that for some  $\eta > 2n$  and  $c_\eta > 0$ , each of the functions  $D^\alpha f^*, D^\alpha p$  with  $|\alpha| \leq J + s$  and  $\sigma_x^2$  satisfies the following decay condition*

$$|f(x)| \leq \frac{c_\eta}{(1 + |x|)^\eta} \quad \forall x \in \mathbb{R}^n. \quad (2.1)$$

If  $\Delta \leq h^{\frac{n(J-s)}{n+2J}}$ , then by taking  $\sigma = h^{\frac{n}{n+2J}}$ , for any  $0 < \delta < 1$ , with confidence  $1 - \delta$ , we have

$$\left\| h^{\frac{2nJ}{n+2J}} f_{\mathbf{z},\sigma} - f^* \right\|_{H^s(\mathbb{R}^n)} \leq \tilde{C}_{q,n,\eta,J,s} \left\{ (1 + M)c_q + c_q c_\eta^2 + c_\eta \|f^*\|_{H^s(\mathbb{R}^n)} \right\} h^{\frac{n(J-s)}{n+2J}} \log \frac{2}{\delta}$$

where  $\tilde{C}_{q,n,\eta,J,s}$  is the constant depending only on  $q, n, \eta, J, s$ .

Theorem 1 will be proved in Section 4 with the constant  $\tilde{C}_{q,n,\eta,J,s}$  given explicitly.

The idea of approximation in Sobolev spaces can be used to learn norms of gradients  $\frac{\partial f^*}{\partial x^i}$  for variable selection and inner products  $\langle \frac{\partial f^*}{\partial x^i}, \frac{\partial f^*}{\partial x^j} \rangle$  for studying covariances [5, 2]. We shall discuss details somewhere else.

It would be interesting to study the randomized sampling for dependent samples [10].

## 3 Sample Error and Approximation Error

The sample error refers to the difference between  $f_{\mathbf{z},\sigma}$  and its data-free limit defined by

$$f_\sigma(x) = \int_{\mathbb{R}^n} \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) f^*(u) \sum_{i \in \mathbb{Z}^n} p(u - t_i) du, \quad x \in \mathbb{R}^n. \quad (3.1)$$

It can be bounded by the following probability inequality for random variables with values in a Hilbert space (see [7] or [6]).

**Lemma 1.** Let  $\mathcal{H}$  be a Hilbert space and  $\{\xi_i\}_{i \in \mathbb{Z}^n}$  be independent random variables on  $Z$  with values in  $\mathcal{H}$ . Assume that for each  $i$ ,  $\|\xi_i\| \leq \widetilde{M} < \infty$  almost surely. Denote  $\widetilde{\sigma}^2 = \sum_{i \in \mathbb{Z}^n} \mathbf{E}(\|\xi_i\|^2)$ . Then for any  $0 < \delta < 1$ , with confidence  $1 - \delta$ ,

$$\left\| \sum_{i \in \mathbb{Z}^n} [\xi_i - \mathbf{E}(\xi_i)] \right\| \leq 2\widetilde{M} \log(2/\delta) + \sqrt{2\widetilde{\sigma}^2 \log(2/\delta)}. \quad (3.2)$$

In our setting, we take  $\{\xi_i\}_{i \in \mathbb{Z}^n}$  to be the random variable on  $Z$  with values in the Hilbert space  $H^s(\mathbb{R}^n)$  given by

$$\begin{aligned} \xi_i &= y_i \Phi\left(\frac{\cdot}{\sigma}, \frac{x_i}{\sigma}\right) - \int_Z y \Phi\left(\frac{\cdot}{\sigma}, \frac{x}{\sigma}\right) d\rho^{(i)} \\ &= y_i \Phi\left(\frac{\cdot}{\sigma}, \frac{x_i}{\sigma}\right) - \int_{\mathbb{R}^n} \Phi\left(\frac{\cdot}{\sigma}, \frac{x}{\sigma}\right) p(x - t_i) f^*(x) dx \end{aligned}$$

Then we can apply Lemma 1 to obtain bounds for sample error. To this end, we need the Sobolev space norm of the function  $\Phi\left(\frac{\cdot}{\sigma}, \frac{x}{\sigma}\right)$ .

**Lemma 2.** Let  $0 < \sigma \leq 1$ . If (1.2) holds, then for any  $x \in \mathbb{R}^n$ , we have

$$\left\| \Phi\left(\frac{\cdot}{\sigma}, \frac{x}{\sigma}\right) \right\|_{H^s(\mathbb{R}^n)} \leq \frac{2c_q(s+1)^n \pi^{n/4}}{\sqrt{(2q-n)\Gamma(n/2)}} \sigma^{\frac{n}{2}-s},$$

where  $\Gamma(t)$  is the Gamma function defined by  $\Gamma(t) = \int_0^\infty r^{t-1} e^{-r} dr$  for  $t > 0$ .

*Proof.* For any  $\alpha \in \mathbb{Z}^n$  with  $0 \leq |\alpha| \leq s$ , we have

$$\begin{aligned} \left\| D^\alpha \left( \Phi\left(\frac{\cdot}{\sigma}, \frac{x}{\sigma}\right) \right) \right\|_{L^2(\mathbb{R}^n)}^2 &= \left\| \sigma^{-|\alpha|} D^\alpha \Phi\left(\frac{\cdot}{\sigma}, \frac{x}{\sigma}\right) \right\|_{L^2(\mathbb{R}^n)}^2 \\ &\leq \sigma^{-2|\alpha|} \int_{\mathbb{R}^n} \frac{c_q^2}{\left(1 + \frac{|u-x|}{\sigma}\right)^{2q}} du \leq \sigma^{n-2|\alpha|} \frac{2\pi^{n/2} c_q^2}{(2q-n)\Gamma(n/2)}. \end{aligned}$$

Since  $0 < \sigma \leq 1$ , we have  $\sigma^{-2|\alpha|} \leq \sigma^{-2s}$  and the desired bound follows.  $\square$

**Proposition 1.** Let  $\Phi$  be a basic window function of type  $(J, s)$  and  $\mathbf{z}$  be a sample. For any  $0 < \delta < 1$ , with confidence  $1 - \delta$ , we have

$$\|f_{\mathbf{z}, \sigma} - f_\sigma\|_{H^s(\mathbb{R}^n)} \leq \frac{8c_q(s+1)^n \pi^{n/4} \sigma^{\frac{n}{2}-s}}{\sqrt{(2q-n)\Gamma(n/2)}} \log \frac{2}{\delta} \left\{ M + \left( \int_{\mathbb{R}^n} [\sigma_x^2 + 2|f^*(x)|^2] \sum_{i \in \mathbb{Z}^n} p(x - t_i) dx \right)^{\frac{1}{2}} \right\}.$$

*Proof.* Since  $\rho_x$  is supported on  $[-M, M]$ ,  $|f^*(x)| \leq M$  for each  $x$ . By Lemma 2, the random variable  $\xi_i = y_i \Phi\left(\frac{\cdot}{\sigma}, \frac{x_i}{\sigma}\right) - \int_{\mathbb{R}^n} \Phi\left(\frac{\cdot}{\sigma}, \frac{x}{\sigma}\right) p(x - t_i) f^*(x) dx$  with values in  $H^s(\mathbb{R}^n)$  satisfies

$$\begin{aligned} \|\xi_i\|_{H^s(\mathbb{R}^n)} &\leq M \left\| \Phi\left(\frac{\cdot}{\sigma}, \frac{x_i}{\sigma}\right) \right\|_{H^s(\mathbb{R}^n)} + \int_{\mathbb{R}^n} \left\| \Phi\left(\frac{\cdot}{\sigma}, \frac{x}{\sigma}\right) \right\|_{H^s(\mathbb{R}^n)} p(x - t_i) |f^*(x)| dx \\ &\leq \frac{4Mc_q(s+1)^n \pi^{n/4}}{\sqrt{(2q-n)\Gamma(n/2)}} \sigma^{\frac{n}{2}-s}. \end{aligned}$$

Write  $\xi_i$  as

$$\xi_i = (y_i - f^*(x_i)) \Phi\left(\frac{\cdot}{\sigma}, \frac{x_i}{\sigma}\right) + f^*(x_i) \Phi\left(\frac{\cdot}{\sigma}, \frac{x_i}{\sigma}\right) - \int_{\mathbb{R}^n} \Phi\left(\frac{\cdot}{\sigma}, \frac{x}{\sigma}\right) p(x - t_i) f^*(x) dx.$$

Then we see from Lemma 2 that for each  $i \in \mathbb{Z}^n$ ,

$$\|\xi_i\|_{H^s(\mathbb{R}^n)} \leq \left\{ |y_i - f^*(x_i)| + |f^*(x_i)| + \int_{\mathbb{R}^n} |f^*(x)| p(x - t_i) dx \right\} \frac{2c_q(s+1)^n \pi^{n/4}}{\sqrt{(2q-n)\Gamma(n/2)}} \sigma^{\frac{n}{2}-s}.$$

It follows from  $(\int_{\mathbb{R}^n} |f^*(x)| p(x - t_i) dx)^2 \leq \int_{\mathbb{R}^n} |f^*(x)|^2 p(x - t_i) dx$  that

$$\sum_{i \in \mathbb{Z}^n} \mathbf{E}(\|\xi_i\|_{H^s(\mathbb{R}^n)}^2) \leq \frac{12c_q^2(s+1)^{2n} \pi^{n/2}}{(2q-n)\Gamma(n/2)} \left\{ \int_{\mathbb{R}^n} [\sigma_x^2 + 2|f^*(x)|^2] \sum_{i \in \mathbb{Z}^n} p(x - t_i) dx \right\} \sigma^{n-2s}.$$

Then our conclusion follows from Lemma 1.  $\square$

Now we turn to the approximation error. We show that,  $f_\sigma$  tends to  $f^* \sum_{i \in \mathbb{Z}^n} p(\cdot - t_i)$  in the space  $H^s(\mathbb{R}^n)$  as  $\sigma$  becomes small.

**Proposition 2.** *Let  $\Phi$  be a basic window function of type  $(J, s)$  defined as Definition 1. Define  $f_\sigma$  by (3.1). If the function  $f^* \sum_{i \in \mathbb{Z}^n} p(\cdot - t_i)$  lies in  $H^{J+s}(\mathbb{R}^n)$ , then for any  $\sigma \leq 1$ , we have*

$$\left\| f_\sigma - \sigma^n f^* \sum_{i \in \mathbb{Z}^n} p(\cdot - t_i) \right\|_{H^s(\mathbb{R}^n)} \leq \frac{2 \cdot 3^{J+s} c_q \pi^{n/2} s!}{(q - J - n) \Gamma(n/2) J!} \left\| f^* \sum_{i \in \mathbb{Z}^n} p(\cdot - t_i) \right\|_{H^{J+s}(\mathbb{R}^n)} \sigma^{n+J-s}. \quad (3.3)$$

*Proof.* Denote  $g(x) = f^*(x) \sum_{i \in \mathbb{Z}^n} p(x - t_i)$ . We apply a Taylor expansion to the function

$$f_\sigma(x) = \int_{\mathbb{R}^n} \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) g(u) du.$$

Let  $u, x \in \mathbb{R}^n$ . Define a univariate function  $h : [0, 1] \rightarrow \mathbb{R}$  as

$$h(t) = g(x + t(u - x)), \quad t \in [0, 1].$$

Then we have

$$g(u) = h(1) = \sum_{\ell=0}^{J-1} \frac{h^{(\ell)}(0)}{\ell!} + \frac{1}{(J-1)!} \int_0^1 (1-v)^{J-1} h^{(J)}(v) dv.$$

Since  $h^{(\ell)}(t) = \sum_{|\alpha|=\ell} (u-x)^\alpha D^\alpha g(x + t(u-x))$ , we see

$$\begin{aligned} f_\sigma(x) &= \int_{\mathbb{R}^n} \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) \sum_{\ell=0}^{J-1} \frac{1}{\ell!} \sum_{|\alpha|=\ell} (u-x)^\alpha D^\alpha g(x) du \\ &\quad + \int_{\mathbb{R}^n} \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) \frac{1}{(J-1)!} \int_0^1 (1-v)^{J-1} \sum_{|\alpha|=J} (u-x)^\alpha D^\alpha g(x + v(u-x)) dv du. \end{aligned}$$

Since  $\int_{\mathbb{R}^n} \Phi(\frac{x}{\sigma}, \frac{u}{\sigma}) du = \sigma^n$ , we know from Property (i) of the basic window function  $\Phi$  that

$$f_\sigma(x) = \sigma^n g(x) + \frac{1}{(J-1)!} \int_0^1 (1-v)^{J-1} \sum_{|\alpha|=J} \left\{ \int_{\mathbb{R}^n} \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) (u-x)^\alpha D^\alpha g(x+v(u-x)) du \right\} dv.$$

To compute the  $H^s(\mathbb{R}^n)$ -norm of  $f_\sigma - \sigma^n g$ , we take  $\beta \in \mathbb{Z}_+^n$  satisfying  $|\beta| \leq s$ . We have

$$\begin{aligned} D^\beta \left\{ \int_{\mathbb{R}^n} \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) (u-x)^\alpha D^\alpha g(x+v(u-x)) du \right\} &= \sum_{j,k,l \in \mathbb{Z}_+^n, j+k+l=\beta} \\ \frac{\beta!}{j!k!l!} \int_{\mathbb{R}^n} \sigma^{-|j|} D^j \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) \frac{\alpha!}{(\alpha-k)!} (-1)^{|k|} (u-x)^{\alpha-k} (1-v)^{|l|} D^{\alpha+l} g(x+v(u-x)) du. \end{aligned}$$

Thus  $\|D^\beta (f_\sigma - \sigma^n g)\|_{L^2(\mathbb{R}^n)}$  is bounded by

$$\sum_{|\alpha|=J} \sum_{j+k+l=\beta} \frac{\alpha!}{(\alpha-k)!} \frac{\beta!}{j!k!l!} \sigma^{-|j|} \frac{1}{(J-1)!} \int_0^1 (1-v)^{J+|l|-1} J_{\alpha,j,k,l}(v) dv,$$

where for  $v \in (0, 1)$ ,

$$J_{\alpha,j,k,l}(v) := \left\| \int_{\mathbb{R}^n} D^j \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) (u-x)^{\alpha-k} D^{\alpha+l} g(x+v(u-x)) du \right\|_{L^2(\mathbb{R}^n)}.$$

We need to estimate  $J_{\alpha,j,k,l}(v)$ . By the Schwarz inequality

$$\begin{aligned} (J_{\alpha,j,k,l}(v))^2 &\leq \int_{\mathbb{R}^n} \left\{ \int_{\mathbb{R}^n} \left| D^j \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) \right| |(u-x)^{\alpha-k}| du \right. \\ &\quad \left. \int_{\mathbb{R}^n} \left| D^j \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) \right| |(u-x)^{\alpha-k}| |D^{\alpha+l} g(x+v(u-x))|^2 du \right\} dx. \end{aligned}$$

Decay condition (1.2) of  $\Phi$  tells us that

$$\int_{\mathbb{R}^n} \left| D^j \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) \right| |(u-x)^{\alpha-k}| du \leq \sigma^{n+|\alpha-k|} \int_{\mathbb{R}^n} \frac{c_q |u|^{|\alpha-k|}}{(1+|u|)^q} du \leq \frac{2c_q \pi^{n/2} \sigma^{n+J-|k|}}{(q+|k|-J-n)\Gamma(n/2)}.$$

Make a variable change  $w = x + v(u-x)$ . We see that

$$\begin{aligned} &\int_{\mathbb{R}^n} \left| D^j \Phi\left(\frac{x}{\sigma}, \frac{u}{\sigma}\right) \right| |(u-x)^{\alpha-k}| |D^{\alpha+l} g(x+v(u-x))|^2 du \\ &\leq \int_{\mathbb{R}^n} \frac{c_q}{(1+|\frac{w-x}{\sigma v}|)^q} \left| \left(\frac{w-x}{v}\right)^{\alpha-k} \right| |D^{\alpha+l} g(w)|^2 v^{-n} dw. \end{aligned}$$

It follows from the Schwarz inequality that

$$(J_{\alpha,j,k,l}(v))^2 \leq \frac{2c_q \pi^{n/2} \sigma^{n+J-|k|}}{(q+|k|-J-n)\Gamma(n/2)} \int_{\mathbb{R}^n} |D^{\alpha+l} g(w)|^2 \sigma^{n+|\alpha-k|} \int_{\mathbb{R}^n} \frac{c_q |u|^{|\alpha-k|}}{(1+|u|)^q} dudw$$

which is bounded by  $\left(\frac{2c_q\pi^{n/2}\sigma^{n+J-|k|}}{(q+|k|-J-n)\Gamma(n/2)}\right)^2 \|D^{\alpha+l}g\|_{L^2(\mathbb{R}^n)}^2$ . Therefore,

$$\begin{aligned} & \|D^\beta(f_\sigma - \sigma^n g)\|_{L^2(\mathbb{R}^n)} \\ & \leq \sum_{|\alpha|=J} \sum_{j+k+l=\beta} \frac{\alpha!}{(\alpha-k)!} \frac{\beta!}{j!k!l!} \frac{1}{(J-1)!} \frac{1}{J+|l|} \frac{2c_q\pi^{n/2}\sigma^{n+J-|j|-|k|}}{(q+|k|-J-n)\Gamma(n/2)} \|D^{\alpha+l}g\|_{L^2(\mathbb{R}^n)} \\ & \leq \frac{2 \cdot 3^{J+s} c_q \pi^{n/2} s! \sigma^{n+J-s}}{(q-J-n)\Gamma(n/2)J!} \sum_{|\alpha|=J} \sum_{l \leq \beta} \|D^{\alpha+l}g\|_{L^2(\mathbb{R}^n)}. \end{aligned}$$

Hence bound (3.3) for  $\|f_\sigma - \sigma^n g\|_{H^s(\mathbb{R}^n)} = \sum_{|\beta| \leq s} \|D^\beta(f_\sigma - \sigma^n g)\|_{L^2(\mathbb{R}^n)}$  follows.  $\square$

## 4 Deriving Convergence Rates

Combining Propositions 1 and 2, we obtain bounds for the total error.

**Proposition 3.** *Under the assumption of Theorem 1, for  $0 < \sigma, h \leq 1$  we have with confidence  $1 - \delta$ ,*

$$\begin{aligned} \left\| \frac{h^n f_{\mathbf{z}, \sigma}}{\sigma^n} - f^* \right\|_{H^s(\mathbb{R}^n)} & \leq C(1 + \Delta)^\eta \log \frac{2}{\delta} h^{\frac{n}{2}} \sigma^{-\frac{n}{2}-s} \\ & \max \left\{ 1, \sigma^{J+\frac{n}{2}} h^{-\frac{n}{2}}, \Delta \sigma^{\frac{n}{2}+s} h^{-\frac{n}{2}}, \Delta^{n+1} \sigma^{\frac{n}{2}+s} h^{-\frac{n}{2}}, \sigma^{\frac{n}{2}+s} h^{\frac{n}{2}+1} \right\} \end{aligned} \quad (4.1)$$

where  $C$  is a constant independent of  $\delta$ ,  $\sigma$ ,  $h$  or  $\Delta$ .

*Proof.* Let us first refine the bound in Proposition 1. Since  $\sigma_x^2$  and  $p$  satisfy decay condition (2.1), we have for  $i \in \mathbb{Z}^n$ ,

$$\int_{\mathbb{R}^n} \sigma_x^2 p(x - t_i) dx \leq \int_{\mathbb{R}^n} \frac{c_\eta}{(1+|x|)^\eta} \frac{c_\eta}{(1+|x-t_i|)^\eta} dx.$$

We divide  $\mathbb{R}^n$  into two domains, one with  $|x - hi| \geq 2\Delta$  and the other with  $|x - hi| < 2\Delta$ .

When  $|x - hi| \geq 2\Delta$ , we have  $|x - t_i| \geq |x - hi| - |t_i - hi| \geq |x - hi| - \Delta \geq \frac{1}{2}|x - hi|$ . It follows that

$$\begin{aligned} & \int_{|x-hi| \geq 2\Delta} \frac{c_\eta}{(1+|x|)^\eta} \frac{c_\eta}{(1+|x-t_i|)^\eta} dx \leq \int_{\mathbb{R}^n} \frac{c_\eta}{(1+|x|)^\eta} \frac{c_\eta}{(1+\frac{1}{2}|x-hi|)^\eta} dx \\ & = \int_{|x| \geq \frac{1}{2}h|i|} \frac{c_\eta}{(1+|x|)^\eta} \frac{c_\eta}{(1+\frac{1}{2}|x-hi|)^\eta} dx + \int_{|x| < \frac{1}{2}h|i|} \frac{c_\eta}{(1+|x|)^\eta} \frac{c_\eta}{(1+\frac{1}{2}|x-hi|)^\eta} dx \\ & \leq \frac{c_\eta}{(1+\frac{1}{2}h|i|)^\eta} \int_{\mathbb{R}^n} \frac{c_\eta}{(1+\frac{1}{2}|x-hi|)^\eta} dx + \frac{c_\eta}{(1+\frac{1}{4}h|i|)^\eta} \int_{\mathbb{R}^n} \frac{c_\eta}{(1+|x|)^\eta} dx \\ & \leq \frac{2^{n+1} c_\eta^2 \pi^{n/2}}{(\eta-n)\Gamma(n/2)} (1+\frac{1}{2}h|i|)^{-\eta} + \frac{2c_\eta^2 \pi^{n/2}}{(\eta-n)\Gamma(n/2)} (1+\frac{1}{4}h|i|)^{-\eta}. \end{aligned}$$

When  $|x - hi| < 2\Delta$ , we have  $|x| > h|i| - 2\Delta$ . Thus if  $|i| > \frac{4\Delta}{h}$ , we have  $|x| > \frac{1}{2}h|i|$  and

$$\int_{|x-hi|<2\Delta} \frac{c_\eta}{(1+|x|)^\eta} \frac{c_\eta}{(1+|x-t_i|)^\eta} dx \leq \frac{c_\eta}{(1+\frac{1}{2}h|i|)^\eta} \int_{\mathbb{R}^n} \frac{c_\eta}{(1+|x-t_i|)^\eta} dx$$

is bounded by  $\frac{2c_\eta^2\pi^{n/2}}{(\eta-n)\Gamma(n/2)}(1+\frac{1}{2}h|i|)^{-\eta}$ .

If  $|i| \leq \frac{4\Delta}{h}$ , we see that

$$\int_{|x-hi|<2\Delta} \frac{c_\eta}{(1+|x|)^\eta} \frac{c_\eta}{(1+|x-t_i|)^\eta} dx \leq \int_{\mathbb{R}^n} \frac{c_\eta^2}{(1+|x|)^\eta} dx \leq \frac{2c_\eta^2\pi^{n/2}}{(\eta-n)\Gamma(n/2)}$$

is bounded by  $\frac{2c_\eta^2\pi^{n/2}}{(\eta-n)\Gamma(n/2)}(1+\frac{1}{2}h|i|)^{-\eta}(1+2\Delta)^\eta$ .

Applying the above estimates together with the following bound from [11]

$$\sum_{i \in \mathbb{Z}^n} (1 + \frac{1}{2}h|i|)^{-\eta} \leq (\sqrt{n} + 1)^n + (4/h)^n \frac{2\pi^{n/2}}{(\eta-n)\Gamma(n/2)},$$

we see that  $\sum_{i \in \mathbb{Z}^n} \int_{\mathbb{R}^n} \sigma_x^2 p(x-t_i) dx$  is bounded by

$$\frac{2c_\eta^2\pi^{n/2}}{(\eta-n)\Gamma(n/2)} \left\{ 2^n + 2^\eta + 1 + (1+2\Delta)^\eta \right\} \left\{ (\sqrt{n} + 1)^n + (8/h)^n \frac{2\pi^{n/2}}{(\eta-n)\Gamma(n/2)} \right\}.$$

In the same way,  $\sum_{i \in \mathbb{Z}^n} \int_{\mathbb{R}^n} |f^*(x)|^2 p(x-t_i) dx$  is bounded by the above same expression with  $c_\eta^2$  replaced by  $c_\eta^3$ .

Therefore from Proposition 1 we see that with confidence  $1 - \delta$ ,

$$\|f_{\mathbf{z},\sigma} - f_\sigma\|_{H^s(\mathbb{R}^n)} \leq \frac{8c_q(s+1)^n \pi^{n/4}}{\sqrt{(2q-n)\Gamma(n/2)}} \left\{ M + c_{\eta,n}(1+\Delta)^{\eta/2} \right\} h^{-\frac{n}{2}} \sigma^{\frac{n}{2}-s} \log \frac{2}{\delta}, \quad (4.2)$$

where  $c_{\eta,n}$  is a constant given by

$$c_{\eta,n} = \frac{(c_\eta^{3/2} + c_\eta)\pi^{n/4} 2^{2+\eta/2}}{\sqrt{(\eta-n)\Gamma(n/2)}} \left\{ (\sqrt{n} + 1)^{n/2} + \frac{8^{n/2}\pi^{n/4}}{\sqrt{(\eta-n)\Gamma(n/2)}} \right\}.$$

In order to use Proposition 2, we need to bound the norm  $\|f^* \sum_{i \in \mathbb{Z}^n} p(\cdot - t_i)\|_{H^{J+s}(\mathbb{R}^n)}$ . Applying decay condition (2.1) again, we see that  $\|f^* \sum_{i \in \mathbb{Z}^n} p(\cdot - t_i)\|_{H^{J+s}(\mathbb{R}^n)}$  is bounded by

$$c_\eta^2 \frac{\{2(J+s)+1\}^n \pi^{n/4}}{\sqrt{(2\eta-n)\Gamma(n/2)}} (1+\Delta)^{\eta 2^{4+\eta}} \left\{ (\sqrt{n} + 1)^n + \frac{8^n \pi^{n/2}}{(\eta-n)\Gamma(n/2)} \right\} h^{-n}.$$

It follows from Proposition 2 that

$$\begin{aligned} \left\| f_\sigma - \sigma^n f^* \sum_{i \in \mathbb{Z}^n} p(\cdot - t_i) \right\|_{H^s(\mathbb{R}^n)} &\leq \frac{\{2(J+s)+1\}^n 3^{J+s+1} s! c_q c_\eta^2 \pi^{3n/4}}{(q-J-n)J! \sqrt{(2\eta-n)\Gamma(n/2)} \Gamma(n/2)} \\ &\quad (1+\Delta)^{\eta 2^{4+\eta}} \left\{ (\sqrt{n} + 1)^n + \frac{8^n \pi^{n/2}}{(\eta-n)\Gamma(n/2)} \right\} \sigma^{n+J-s} h^{-n}. \end{aligned} \quad (4.3)$$

Finally, we must study the difference between  $\sum_{i \in \mathbb{Z}^n} p(\cdot - t_i)$  and  $\sum_{i \in \mathbb{Z}^n} p(\cdot - hi)$  by the restriction  $\sup_i |t_i - hi| \leq \Delta$ . For  $x \in \mathbb{R}^n$ ,

$$\begin{aligned} \left| \sum_{i \in \mathbb{Z}^n} p(x - hi) - \sum_{i \in \mathbb{Z}^n} p(x - t_i) \right| &\leq \sum_{i \in \mathbb{Z}^n} |p(x - hi) - p(x - hi - (t_i - hi))| \\ &= \sum_{i \in \mathbb{Z}^n} \left| \int_0^1 \sum_{|\alpha|=1} (t_i - hi)^\alpha D^\alpha p(x - hi - u(t_i - hi)) du \right| \\ &\leq \sum_{i \in \mathbb{Z}^n} \int_0^1 \frac{n\Delta c_\eta}{(1 + |x - hi - u(t_i - hi)|)^\eta} du. \end{aligned}$$

For every  $x \in \mathbb{R}^n$ , we can find some  $k \in \mathbb{Z}^n$  such that  $x - hk \in [-\frac{h}{2}, \frac{h}{2}]^n$ . Then  $|x - hi| = |x - hk + h(k - i)| \geq \frac{1}{2}|k - i|h$ . Separate  $\sum_{i \in \mathbb{Z}^n}$  into two parts  $\sum_{|x - hi| \geq 2\Delta}$  (where  $|x - hi - u(t_i - hi)| \geq |x - hi| - \Delta \geq \frac{1}{2}|x - hi|$  for  $u \in [0, 1]$ ) and  $\sum_{|x - hi| < 2\Delta}$ . We have

$$\begin{aligned} \left| \sum_{i \in \mathbb{Z}^n} p(x - hi) - \sum_{i \in \mathbb{Z}^n} p(x - t_i) \right| &\leq \sum_{i \in \mathbb{Z}^n} \frac{n\Delta c_\eta}{(1 + \frac{1}{2}|x - hi|)^\eta} + \left(\frac{4\Delta}{h}\right)^n n\Delta c_\eta \\ &\leq \sum_{i \in \mathbb{Z}^n} \frac{n\Delta c_\eta}{(1 + \frac{1}{4}|k - i|h)^\eta} + \left(\frac{4\Delta}{h}\right)^n n\Delta c_\eta \\ &\leq \left\{ (\sqrt{n} + 1)^n + \frac{2\pi^{n/2}8^n}{(\eta - n)\Gamma(n/2)} \right\} n c_\eta h^{-n} \Delta + 4^n n c_\eta h^{-n} \Delta^{n+1}. \end{aligned}$$

Combining an estimation in [11] for  $|h^n \sum_{i \in \mathbb{Z}^n} h^n p(x - hi) - 1|$ , we have

$$\left| h^n \sum_{i \in \mathbb{Z}^n} p(x - t_i) - 1 \right| \leq c_\eta \{c'_{\eta,n} \Delta + 4^n n \Delta^{n+1} + (c'_{\eta,n} + n2^n) h^{n+1}\},$$

where  $c'_{\eta,n}$  is the constant given by

$$c'_{\eta,n} = \left\{ (\sqrt{n} + 1)^n + \frac{2\pi^{n/2}8^n}{(\eta - n)\Gamma(n/2)} \right\} n.$$

This in connection with (4.2) and (4.3) tells us that with confidence  $1 - \delta$ , the total error

$\left\| \frac{h^n f_{\mathbf{z}, \sigma}}{\sigma^n} - f^* \right\|_{H^s(\mathbb{R}^n)}$  is bounded by

$$\begin{aligned} &\frac{8c_q(s+1)^n \pi^{n/4}}{\sqrt{(2q-n)\Gamma(n/2)}} \{M + c_{\eta,n}(1 + \Delta)^{\eta/2}\} h^{\frac{n}{2}} \sigma^{-\frac{n}{2}-s} \log \frac{2}{\delta} \\ &+ c_\eta \|f^*\|_{H^s(\mathbb{R}^n)} \{c'_{\eta,n} \Delta + 4^n n \Delta^{n+1} + (c'_{\eta,n} + n2^n) h^{n+1}\} \\ &+ \frac{\{2(J+s)+1\}^n 3^{J+s+1} s! c_q c_\eta^2 \pi^{3n/4} (1 + \Delta)^\eta 2^{4+\eta}}{(q-J-n)J! \sqrt{(2\eta-n)\Gamma(n/2)\Gamma(n/2)}} \left\{ (\sqrt{n} + 1)^n + \frac{8^n \pi^{n/2}}{(\eta - n)\Gamma(n/2)} \right\} \sigma^{J-s}. \end{aligned}$$

So desired bound (4.1) holds true with the constant  $C$  taken to be

$$\begin{aligned} C &= 40c_q(s+1)^n \{M + c_{\eta,n}\} + c_\eta \|f^*\|_{H^s(\mathbb{R}^n)} \{2c'_{\eta,n} + n4^n + n2^n\} \\ &\quad + \{2(J+s)+1\}^n 3^{J+s+5} s! c_q c_\eta^2 2^{6+\eta} \{(\sqrt{n} + 1)^n + 8^n\}. \end{aligned}$$

This proves Proposition 3. □

Now we can prove Theorem 1 easily.

*Proof of Theorem 1.* Since  $\Delta \leq h^{\frac{n(J-s)}{n+2J}} \leq 1$  and  $\sigma = h^{\frac{n}{n+2J}}$  and , we have  $\sigma^{J+\frac{n}{2}}h^{-\frac{n}{2}} = 1$  and  $\Delta\sigma^{\frac{n}{2}+s}h^{-\frac{n}{2}} = 1$ . So we get

$$\max \left\{ 1, \sigma^{J+\frac{n}{2}}h^{-\frac{n}{2}}, \Delta\sigma^{\frac{n}{2}+s}h^{-\frac{n}{2}}, \Delta^{n+1}\sigma^{\frac{n}{2}+s}h^{-\frac{n}{2}}, \sigma^{\frac{n}{2}+s}h^{\frac{n}{2}+1} \right\} = 1.$$

Then the conclusion of Theorem 1 follows from Proposition 3 with the constant

$$\begin{aligned} \tilde{C}_{q,n,\eta,J,s} = & 2^\eta \left\{ 40(s+1)^n \{1 + c_{\eta,n}\} + 2c'_{\eta,n} + n4^n + n2^n \right. \\ & \left. + \{2(J+s)+1\}^n 3^{J+s+5} s! 2^{6+\eta} [(\sqrt{n}+1)^n + 8^n] \right\}. \end{aligned}$$

The proof of Theorem 1 is complete. □
